## Today: More on Scheduling Algorithms

- Goals for scheduling
- FCFS & Round Robin
- SJF
- Multilevel Feedback Queues
- Lottery Scheduling

#### Computer Science

CS377: Operating Systems

Lecture 5, page 2

# Short Term Scheduling

- The kernel runs the scheduler at least when
  - 1. a process switches from running to waiting,
  - 2. an interrupt occurs, or
  - 3. a process is created or terminated.
- Non-preemptive system: the scheduler must wait for one of these events
- **Preemptive system**: the scheduler can interrupt a running process

#### Computer Science

CS377: Operating Systems

Lecture 5, page 3

#### Criteria for Comparing Scheduling Algorithms

- **CPU Utilization** The percentage of time that the CPU is busy.
- **Throughput** The number of processes completing in a unit of time.
- **Turnaround time** The length of time it takes to run a process from initialization to termination, including all the waiting time.
- **Waiting time** The total amount of time that a process is in the ready queue.
- **Response time** The time between when a process is ready to run and its next I/O request.

# **Scheduling Policies**

- Ideally, choose a CPU scheduler that optimizes all criteria simultaneously (utilization, throughput,..), but this is not generally possible
- Instead, choose a scheduling algorithm based on its ability to satisfy a policy
- Minimize average response time provide output to the user as quickly as possible and process their input as soon as it is received.
- Minimize variance of response time in interactive systems, predictability may be more important than a low average with a high variance.
- Maximize throughput two components
  - minimize overhead (OS overhead, context switching)
  - efficient use of system resources (CPU, I/O devices)
- Minimize waiting time give each process the same amount of time on the processor. This might actually increase average response time.

Lecture 5, page 4

CS377: Operating Systems

#### **Scheduling Policies Simplifying Assumptions** FCFS: First Come, First Served • One process per user • One thread per process Processes are independent **SJF:** Shortest Job First Researchers developed these algorithms in the 70's when these assumptions were more realistic, and it is still an open problem how to relax these assumptions. picks winning ticket. Computer Science CS377: Operating Systems Lecture 5, page 6 Computer Science CS377: Operating Systems **Scheduling Policies** Time FCFS: First-Come-First-Served (or FIFO: First-In-First-Out)

- The scheduler executes jobs to completion in arrival order.
- In early FCFS schedulers, the job did not relinquish the CPU even when it was doing I/O.
- We will assume a FCFS scheduler that runs when processes are blocked on I/O, but that is non-preemptive, i.e., the job keeps the CPU until it blocks (say on an I/O device).

# Scheduling Algorithms: A Snapshot

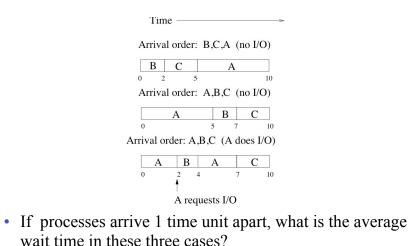

Round Robin: Use a time slice and preemption to alternate jobs.

Multilevel Feedback Queues: Round robin on each priority queue.

Lottery Scheduling: Jobs get tickets and scheduler randomly

Lecture 5, page 7

# FCFS Scheduling Policy: Example

Computer Science CS377: Operating Systems

Computer Science

#### FCFS: Advantages and Disadvantages

#### Advantage: simple

#### **Disadvantages:**

- average wait time is highly variable as short jobs may wait behind long jobs.
- may lead to poor overlap of I/O and CPU since CPU-bound processes will force I/O bound processes to wait for the CPU, leaving the I/O devices idle

CS377: Operating Systems

Lecture 5, page 10

# **Round Robin Scheduling**

- · Variants of round robin are used in most time sharing systems
- Add a timer and use a preemptive policy.
- After each time slice, move the running thread to the back of the queue.
- Selecting a time slice:
  - Too large waiting time suffers, degenerates to FCFS if processes are never preempted.
  - Too small throughput suffers because too much time is spent context switching.
- => Balance these tradeoffs by selecting a time slice where context switching is roughly 1% of the time slice.
- Today: typical time slice= 10-100 ms, context switch time= 0.1-1ms
- Advantage: It's fair; each job gets an equal shot at the CPU.
- Disadvantage: Average waiting time can be bad.

CS377: Operating Systems

## SJF/SRTF: Shortest Job First

- Schedule the job that has the least (expected) amount of work (CPU time) to do until its next I/O request or termination.
- Advantages:
  - Provably optimal with respect to minimizing the average waiting time
  - Works for preemptive and non-preemptive schedulers
  - Preemptive SJF is called SRTF shortest remaining time first
  - => I/O bound jobs get priority over CPU bound jobs
- Disadvantages:
  - Impossible to predict the amount of CPU time a job has left
  - Long running CPU bound jobs can starve

Lecture 5, page 16

# SJF: Example

•5 jobs, of length 50, 40, 30, 20, and 10 seconds each, time slice 1 second, context switch time of 0 seconds

## Multilevel Feedback Queues (MLFQ)

- Multilevel feedback queues use past behavior to predict the future and assign job priorities
  - => overcome the prediction problem in SJF
- If a process is I/O bound in the past, it is also likely to be I/O bound in the future (programs turn out not to be random.)
- To exploit this behavior, the scheduler can favor jobs that have used the least amount of CPU time, thus approximating SJF.
- This policy is **adaptive** because it relies on past behavior and changes in behavior result in changes to scheduling decisions.

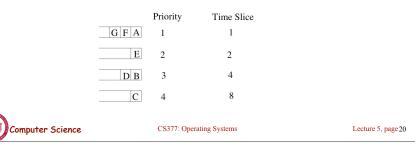

CS377: Operating Systems

Lecture 5, page 19

#### Approximating SJF: Multilevel Feedback Queues

- Multiple queues with different priorities.
- Use Round Robin scheduling at each priority level, running the jobs in highest priority queue first.
- Once those finish, run jobs at the next highest priority queue, etc. (Can lead to starvation.)
- Round robin time slice increases exponentially at lower priorities.

# Adjusting Priorities in MLFQ

- Job starts in highest priority queue.
- If job's time slices expires, drop its priority one level.
- If job's time slices does not expire (the context switch comes from an I/O request instead), then increase its priority one level, up to the top priority level.
- $\Rightarrow$  CPU bound jobs drop like a rock in priority and I/O bound jobs stay at a high priority.

#### Multilevel Feedback Queues:Example 1

•3 jobs, of length 30, 20, and 10 seconds each, initial time slice 1 second, context switch time of 0 seconds, all CPU bound (no I/O), queues

# **Improving Fairness**

Since SJF is optimal, but unfair, any increase in fairness by giving long jobs a fraction of the CPU when shorter jobs are available will degrade average waiting time.

Possible solutions:

- Give each queue a fraction of the CPU time. This solution is only fair if there is an even distribution of jobs among queues.
- Adjust the priority of jobs as they do not get serviced (Unix originally did this.) This ad hoc solution avoids starvation but average waiting time suffers when the system is overloaded because all the jobs end up with a high priority,.

CS377: Operating Systems
```

Lecture 5, page 26

# Lottery Scheduling

- Give every job some number of lottery tickets.
- On each time slice, randomly pick a winning ticket.
- On average, CPU time is proportional to the number of tickets given to each job.
- Assign tickets by giving the most to short running jobs, and fewer to long running jobs (approximating SJF). To avoid starvation, every job gets at least one ticket.
- Degrades gracefully as load changes. Adding or deleting a job affects all jobs proportionately, independent of the number of tickets a job has.

CS377: Operating Systems

Lecture 5, page 27

# Lottery Scheduling: Example

• Short jobs get 10 tickets, long jobs get 1 ticket each.

| # short jobs/ | % of CPU each  | % of CPU each |
|---------------|----------------|---------------|
| # long jobs   | short job gets | long job gets |
| 1/1           | 91%            | 9%            |
| 0/2           |                |               |
| 2/0           |                |               |
| 10/1          |                |               |
| 1/10          |                |               |

# Lottery Scheduling Example

• Short jobs get 10 tickets, long jobs get 1 ticket each.

| # short jobs/ | % of CPU each  | % of CPU each |
|---------------|----------------|---------------|
| # long jobs   | short job gets | long job gets |
| 1/1           | 91% (10/11)    | 9% (1/11)     |
| 0/2           |                | 50% (1/2)     |
| 2/0           | 50% (10/20)    |               |
| 10/1          | 10% (10/101)   | < 1% (1/101)  |
| 1/10          | 50% (10/20)    | 5% (1/20)     |

# Summary of Scheduling Algorithms:

- FCFS: Not fair, and average waiting time is poor.
- Round Robin: Fair, but average waiting time is poor.
- **SJF:** Not fair, but average waiting time is minimized assuming we can accurately predict the length of the next CPU burst. Starvation is possible.
- Multilevel Queuing: An implementation (approximation) of SJF.
- Lottery Scheduling: Fairer with a low average waiting time, but less predictable.
- ⇒ Our modeling assumed that context switches took no time, which is unrealistic.
