

- OS reacts to changes in hardware, and can motivate changes.
- History lesson in change.
- An operating system is the interface between the user and the architecture.

## Last Class: Introduction to Operating Systems

- Office: LGR C A310, Ph: 413 545 0728, Email: vikas@cs.umass.edu
- Th: 1:00-2:00, Fr: 10:00-11:00, LGR T 224

- **TA Office Hours**

- **TA:** Vikas Khandelwal

- Office: LGR C A255, Ph: 413 577 0850, Email: shenoy@cs.umass.edu
- TuTh: 3:45-4:45, LGR C A255, or by appointment

- **My Office Hours**

## Announcements

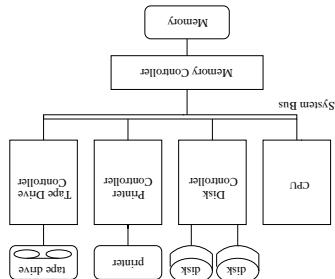

- 1. **Concurrency:** Doing many things simultaneously (I/O, processing, multiple programs, etc.)
- 2. **I/O devices:** Let the CPU work while a slow I/O device is working
- 3. **Memory management:** OS coordinates allocation of memory and moving data between disk and main memory.
- 4. **Files:** OS coordinates how disk space is used to store multiple files
- 5. **Distributed systems & networks:** allow a group of workstations to work together on distributed hardware

## Modern Operating System Functionality

- Basic OS Functionality
- Basic Architecture reminder
- What the OS can do is dictated in part by the architecture.
- Architectural support can greatly simplify or complicate the OS.

## Today: OS and Computer Architecture

- CPU: the processor that performs the actual computation
- I/O devices: terminal, disks, video board, printer, etc.
- Memory: RAM containing data and programs used by the CPU
- System bus: communication medium between CPU, memory, and peripherals

## Generic Computer Architecture

- **OS as history teacher:** learning from past to predict the future, i.e., OS design tradeoffs change with technology.
- **OS as complex system:** keeping OS design and implementation as simple as possible is the key to getting the OS to work.
- **OS as government:** protecting users from each other, allocating resources efficiently and fairly, and providing secure and safe communication.
- **OS as juggler:** providing the illusion of a dedicated machine with infinite memory and CPU.

## Summary of Operating System Principles

- Protected instructions can only be executed in kernel mode.
- A status bit in a protected processor register indicates the mode.

The hardware must support at least kernel and user mode.

but in kernel mode, the OS can do all these things.

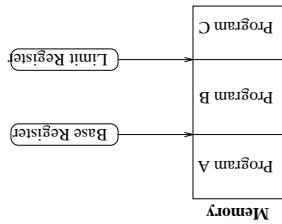

- halt the machine
- disable and enable interrupts
- set the mode bits that determine user or kernel mode etc.)
- use instructions that manipulate the state of memory (page table pointers, TLB load,
- address I/O directly

**Kernel mode vs. User mode:** To protect the system from aberrant users and processors, some instructions are restricted to use only by the OS. Users may not

## Protection

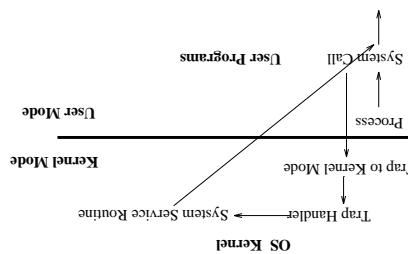

OS Service	Hardware Support	Protection	Interrupts	I/O	Scheduling, error recovery, billing	Synchronization	Virtual memory
		Kernel/User mode Protected instructions Base and Limit Registers Interrupt Vectors Trap instructions and trap vectors Interrupts or Memory-Mapping Timer Synchronization Translation lookaside buffers					

## Architectural Features Motivated by OS Services

- The CPU checks each user reference (instruction and data addresses), ensuring it falls between the base and limit register values.
- Base and limit registers are loaded by the OS before starting a program.
- The simplest technique is to use base and limit registers.
  - protect the OS from user programs.
  - protect user programs from each other, and
- Architecture must provide support so that the OS can

## Memory Protection

- The architecture must also provide a way to return to user mode when finished.
- The architecture must permit the OS to verify the caller's parameters.
- The handler saves caller's state (PC, mode bit) so it can restore control to the user process.
- The trap handler uses the trap handler in the OS kernel.
- The trap handler uses the trap parameter to the system call to jump to the appropriate handler (I/O, Terminal, etc.).
- Causes a trap, which vectors (jumps) to the trap handler in the OS kernel.

- **System call:** OS procedure that executes privileged instructions (e.g., I/O)

## Crossing Protection Boundaries

- Traps are a performance optimization. A less efficient solution is to insert extra instructions into the code everywhere a special condition could arise.
- Modern OS use Virtual Memory traps for many functions: debugging, distributed VM, garbage collection, copy-on-write, etc.

0:	0x00080000	Illegal Address	Memory Violation	Illegal Instruction	System Call	...
1:	0x00100000					3:
2:	0x001100480					
3:	0x00123010					

Trap Vector:

## Traps

- On detecting a trap, the hardware
  - Examples: page fault, write to a read-only page, overflow, systems call
- Traps: special conditions detected by the architecture
  - Transfers control to appropriate trap handler (OS routine)
  - Saves the state of the process (PC, stack, etc.)
  - The CPU indexes the memory-mapped trap vector with the trap number,
  - then jumps to the address given in the vector, and
    - \* starts to execute at that address.
    - \* On completion, the OS resumes execution of the process

## Traps

- Writing the data directly into memory.
- Access to the device then becomes almost as fast and convenient as writing the data directly into memory.
- PCs (no virtual memory), reserve a part of the memory and put the device manager in that memory (e.g., all the bits for a video frame for a video controller).
- PCs (no virtual memory), reserve a part of the memory and put the I/O code and data into memory.
- Enables direct access to I/O controller (vs. being required to move the I/O code and data into memory).

## Memory-Mapped I/O

- CPU stops whatever it was doing and the OS processes the I/O device's interrupt.
- When the I/O device completes the command, it issues an interrupt.
- CPU issues commands to I/O devices, and continues autonomously.
- Each I/O device has a little processor inside it that enables it to run

## I/O Control

0:	0x2ff00000	Keyboard
1:	0xfc0000b0	Mouse
2:	0xd2f00000	Timer
3:	0x2ffc6810	Disk 1
...		

### Interrupt Vector:

- At each timer interrupt, the CPU chooses a new process to execute.
- CPU protected from being hogged using timer interrupts that occur at say every 100 microseconds.
- Accounting and billing
- Time of Day

### Timer

## Timer & Atomic Instructions

1. Save critical CPU state (hardware state),
2. Disable interrupts,
3. Save state that interrupt handler will modify (software state)
4. Invoke interrupt handler using the *in-memory Interrupt Vector*
5. Restore software state
6. Enable interrupts
7. Restore hardware state, and continue execution of interrupted process

### CPU takes an interrupt.

- Device puts an interrupt signal on the bus when it is finished.

asynchronously with the main CPU.

- Device controller has its own small processor which executes

## Interrupt based asynchronous I/O

- In order for pieces of the program to be located and loaded without causing a major disruption to the program, the hardware provides a translation lookaside buffer to speed the lookup.
- The OS must keep track of which pieces are in which parts of physical memory and which pieces are on disk.
- Instead, pieces of the program are loaded as they are needed.
- Virtual memory allows users to run programs without loading the entire program in memory at once.

## Virtual Memory

2. A special instruction that executes atomically (e.g., `test&set`).
1. Architecture mechanism to disable interrupts before sequence, execute sequence, enable interrupts again.
- Architecture must provide a guarantee that short sequences of instructions (e.g., read-modify-write) execute atomically. Two solutions:
- OS must be able to synchronize cooperation, concurrent processes.
  - Interrupts interfere with executing processes.

## Synchronization

Keep your architecture book on hand.

OS provides an interface to the architecture, but also requires some additional functionality from the architecture.

⇒ The OS and hardware combine to provide many useful and important features.

## Summary
