Today: Distributed File Systems

- Overview of stand-alone (UNIX) file systems
- Issues in distributed file systems
- Next two classes: case studies of distributed file systems
 - NFS
 - Coda
 - xFS
 - Log-structured file systems (time permitting)
 - HDFS; object storage systems

CS677: Distributed OS

Lecture 19, page 1

File System Basics

- File: named collection of logically related data
 - Unix file: an uninterpreted sequence of bytes
- File system:
 - Provides a logical view of data and storage functions
 - User-friendly interface
 - Provides facility to create, modify, organize, and delete files
 - Provides sharing among users in a controlled manner
 - Provides protection

Unix File System Review

- User file: linear array of bytes. No records, no file types
- Directory: special file not directly writable by user
- File structure: directed acyclic graph [directories may not be shared, files may be shared (why?)]
- Directory entry for each file
 - File name
 - inode number
 - Major device number
 - Minor device number
- All inodes are stored at a special location on disk [super block]
 - Inodes store file attributes and a multi-level index that has a list of disk block locations for the file

CS677: Distributed OS

Lecture 19, page 3

Inode Structure

- Fields
 - Mode
 - Owner_ID, group_id
 - Dir_file
 - Protection bits
 - Last access time, last write time, last inode time
 - Size, no of blocks
 - Ref cnt
 - Address[0], ... address[14]
 - Multi-level index: 12 direct blocks, one single, double, and triple indirect blocks

CS677: Distributed OS Lecture 19, page 4

Distributed File Systems

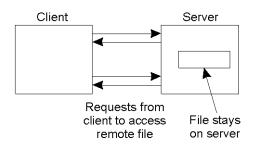

- File service: specification of what the file system offers
 - Client primitives, application programming interface (API)
- File server: process that implements file service
 - Can have several servers on one machine (UNIX, DOS,...)
- Components of interest
 - File service
 - Directory service

CS677: Distributed OS

Lecture 19, page 5

File Service

1. File moved to client

Server

Old file

New file

2. Accesses are done on client

3. When client is done, file is returned to server

- Remote access model
 - Work done at the server
- Stateful server (e.g., databases)
- Consistent sharing (+)
- Server may be a bottleneck (-)
- Need for communication (-)

- Upload/download mode
 - Work done at the client
- Stateless server
- •Simple functionality (+)
- •Moves files/blocks, need storage (-)

System Structure: Server Type

Stateless server

- No information is kept at server between client requests
- All information needed to service a requests must be provided by the client with each request (what info?)
- More tolerant to server crashes

Stateful server

- Server maintains information about client accesses
- Shorted request messages
- Better performance
- Idempotency easier
- Consistency is easier to achieve

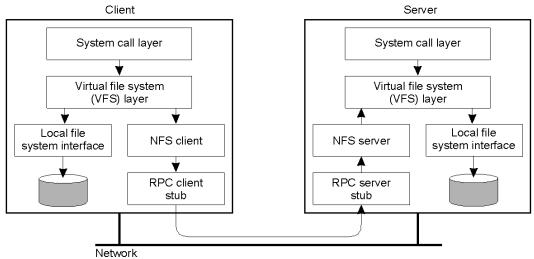

CS677: Distributed OS

Lecture 19, page 7

NFS Architecture

- Sun's Network File System (NFS) widely used distributed file system
- Uses the virtual file system layer to handle local and remote files

NFS Operations

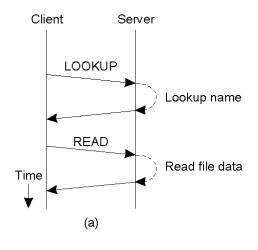

Operation	v3	v4	Description	
Create	Yes	No	Create a regular file	
Create	No	Yes	Create a nonregular file	
Link	Yes	Yes	Create a hard link to a file	
Symlink	Yes	No	Create a symbolic link to a file	
Mkdir	Yes	No	Create a subdirectory in a given directory	
Mknod	Yes	No	Create a special file	
Rename	Yes	Yes	Change the name of a file	
Rmdir	Yes	No	Remove an empty subdirectory from a directory	
Open	No	Yes	Open a file	
Close	No	Yes	Close a file	
Lookup	Yes	Yes	Look up a file by means of a file name	
Readdir	Yes	Yes	Read the entries in a directory	
Readlink	Yes	Yes	Read the path name stored in a symbolic link	
Getattr	Yes	Yes	Read the attribute values for a file	
Setattr	Yes	Yes	Set one or more attribute values for a file	
Read	Yes	Yes	Read the data contained in a file	
Write	Yes	Yes	Write data to a file	

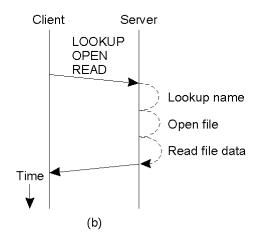

CS677: Distributed OS

Lecture 19, page 9

Communication

- a) Reading data from a file in NFS version 3.
- b) Reading data using a compound procedure in version 4.

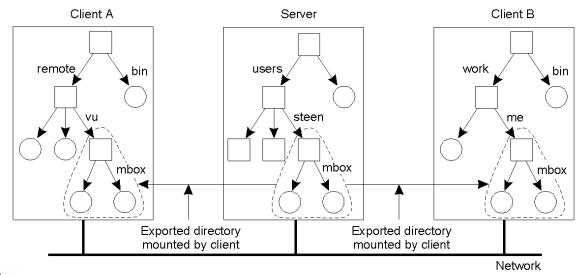

Both versions use Open Network Computing (ONC) RPCs

- One RPC per operation (NFS v3); multiple operations supported in v4.

Naming: Mount Protocol

- NFS uses the mount protocol to access remote files
 - Mount protocol establishes a local name for remote files
 - Users access remote files using local names; OS takes care of the mapping

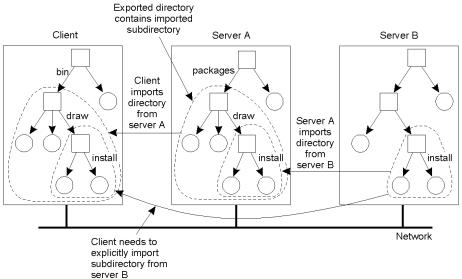

CS677: Distributed OS

Lecture 19, page 11

Naming: Crossing Mount Points

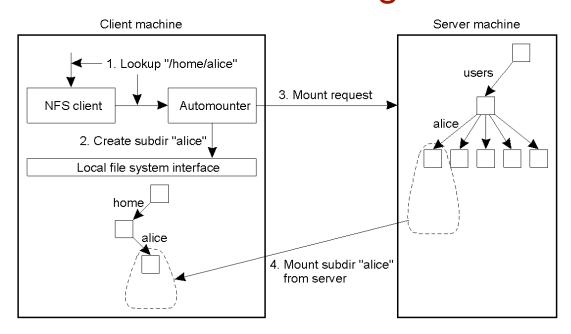

- Mounting nested directories from multiple servers
- NFS v3 does not support transitive exports (for security reasons)
 - NFS v4 allows clients to detects crossing of mount points, supports recursive lookups

Computer Science

CS677: Distributed OS

Automounting

Automounting: mount on demand

CS677: Distributed OS

Lecture 19, page 13

File Attributes (1)

Attribute	Description	
TYPE	The type of the file (regular, directory, symbolic link)	
SIZE	The length of the file in bytes	
CHANGE	Indicator for a client to see if and/or when the file has changed	
FSID	Server-unique identifier of the file's file system	

- Some general mandatory file attributes in NFS.
 - NFS modeled based on Unix-like file systems
 - Implementing NFS on other file systems (Windows) difficult
 - $-\ NFS\ v4$ enhances compatibility by using mandatory and recommended attributes

File Attributes (2)

Attribute	Description		
ACL	an access control list associated with the file		
FILEHANDLE	The server-provided file handle of this file		
FILEID	A file-system unique identifier for this file		
FS_LOCATIONS	Locations in the network where this file system may be found		
OWNER	The character-string name of the file's owner		
TIME_ACCESS	Time when the file data were last accessed		
TIME_MODIFY	Time when the file data were last modified		
TIME_CREATE	Time when the file was created		

• Some general recommended file attributes.

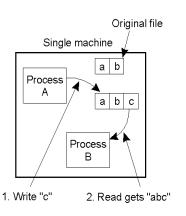

CS677: Distributed OS

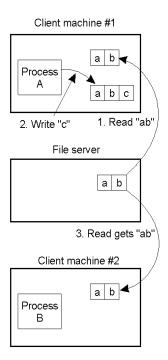

Lecture 19, page 15

Semantics of File Sharing

- a) On a single processor, when a *read* follows a *write*, the value returned by the *read* is the value just written.
- b) In a distributed system with caching, obsolete values may be returned.

(a)

(b)

Semantics of File Sharing

Method	Comment
UNIX semantics	Every operation on a file is instantly visible to all processes
Session semantics	No changes are visible to other processes until the file is closed
Immutable files	No updates are possible; simplifies sharing and replication
Transaction	All changes occur atomically

- Four ways of dealing with the shared files in a distributed system.
 - NFS implements session semantics
 - Can use remote/access model for providing UNIX semantics (expensive)
 - Most implementations use local caches for performance and provide session semantics

CS677: Distributed OS

Lecture 19, page 17

File Locking in NFS

Operation	Description		
Lock	Creates a lock for a range of bytes (non-blocking_		
Lockt	Test whether a conflicting lock has been granted		
Locku	Remove a lock from a range of bytes		
Renew	Renew the lease on a specified lock		

- NFS supports file locking
 - Applications can use locks to ensure consistency
 - Locking was not part of NFS until version 3
 - NFS v4 supports locking as part of the protocol (see above table)

File Locking: Share Reservations

Current file denial state

Request access

	NONE	READ	WRITE	вотн
READ	Succeed	Fail	Succeed	Fail
WRITE	Succeed	Succeed	Fail	Fail
вотн	Succeed	Fail	Fail	Fail

(a)

Requested file denial state

Current access state

·	NONE	READ	WRITE	вотн
READ	Succeed	Fail	Succeed	Fail
WRITE	Succeed	Succeed	Fail	Fail
вотн	Succeed	Fail	Fail	Fail

(b)

- The result of an *open* operation with share reservations in NFS.
- a) When the client requests shared access given the current denial state.
- b) When the client requests a denial state given the current file access state.

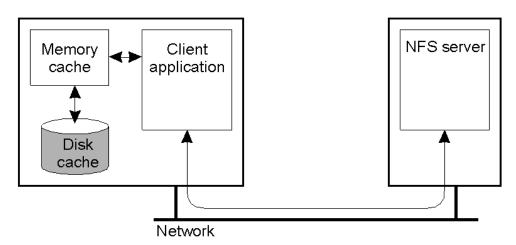

CS677: Distributed OS

Lecture 19, page 19

Client Caching

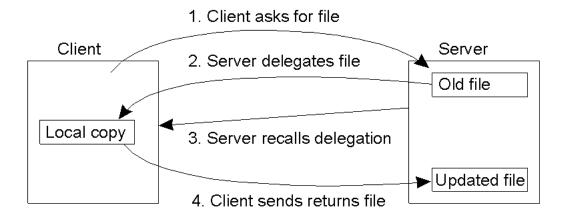

- Client-side caching is left to the implementation (NFS does not prohibit it)
 - Different implementation use different caching policies
 - Sun: allow cache data to be stale for up to 30 seconds

Client Caching: Delegation

- NFS V4 supports open delegation
 - Server delegates local open and close requests to the NFS client
 - Uses a callback mechanism to recall file delegation.

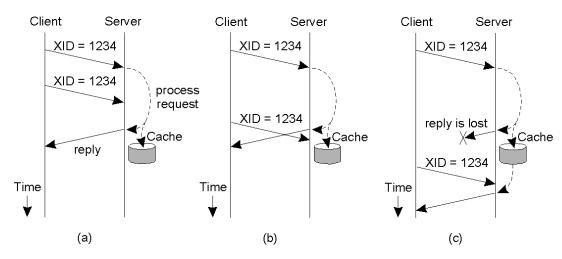

CS677: Distributed OS

Lecture 19, page 21

Lecture 19, page 22

RPC Failures

- Three situations for handling retransmissions: use a duplicate request cache
- a) The request is still in progress
- b) The reply has just been returned
- c) The reply has been some time ago, but was lost.

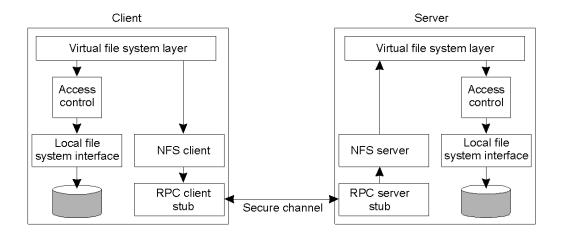

Use a duplicate-request cache: transaction Ids on RPCs, results cached

CS677: Distributed OS

Security

- The NFS security architecture.
 - Simplest case: user ID, group ID authentication only

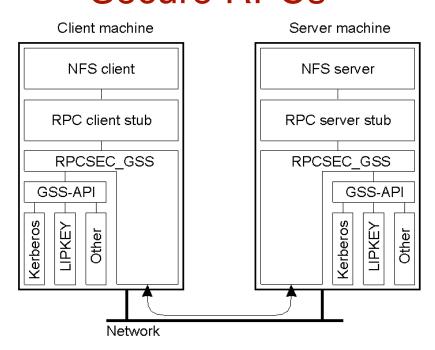

CS677: Distributed OS

Lecture 19, page 23

Secure RPCs

Secure RPC in NFS version 4.

Replica Servers

- NFS ver 4 supports replications
- Entire file systems must be replicated
- FS_LOCATION attribute for each file
- Replicated servers: implementation specific

CS677: Distributed OS
